Abstract—In this paper we present the “continuum model”. Our approach is designed to handle dynamic phenomena extending the 4D-fluent approach with the use of semantic web technologies. In our approach we represent dynamic entities as constituted by time slices each with semantic, geometric and temporal components. Our model is able to link the diverse representations of an entity and allows the inference of qualitative information from quantitative one. The results of the inference are later added to the ontology in order to enhance the knowledge base. The model has been implemented using OWL and SWRL. Our preliminary results are promising and we plan to further develop the model in the near future to increase the number of suitable data sources.

Keywords—spatio-temporal, semantics, GIS, perdurantism

I. INTRODUCTION

For the design of a spatio-temporal knowledge system, it is necessary to consider the three components of an entity representation: 1) The spatial aspect consisting in the geometry, 2) the temporal aspect which defines the interval of existence of the geometries and finally 3) the semantic aspect which defines a meaning for the entity beyond the purely geographic one [1]. Currently available GIS tools lack the capacity to perform inference or reasoning on information from spatial-temporal dynamic phenomena. An alternative to classic GIS tools are Semantic Web technologies, tools specifically designed to perform reasoning and inference. In this research we use Semantic Web technologies to develop the “continuum model”, an ontology that allows us to represent diverse dynamic entities and analyse the relations that might evolve among them.

Traditionally ontologies are static in the sense that the information represented in them does not change in time or in space. In this paper we introduce the continuum model, an ontology that extends the 4D-fluent providing it with the required capabilities to keep track of spatial and semantic evolution of entities along time.

In Section II we discuss related work in the field of spatio-temporal knowledge representation. In Section III we introduce the continuum model, we present the model specification using Tarski-style semantics, in section IV we describe how the model operates using an example and later we indicate our conclusions and future work.

II. RELATED WORK

The development of a spatial-temporal knowledge system involves two aspects, first the representation of the knowledge and second, the necessary mechanisms to perform analysis and querying.

A. Representing temporal data

The two main philosophical theories concerning the representation of object persistence over time are: *endurantism* and *perdurantism*. The first one, *endurantism*, considers objects as three dimensional entities that exist wholly at any given point of their life. On the other hand, *perdurantism*, also known as the four dimensional view, considers that entities have temporal parts, “time slices” [2]. From a perdurantism point of view the temporal dimension of an entity is composed by all its time slices. It therefore represents the different properties of an entity over time as *fluent*. A *fluent* is a property valid only during certain intervals or moments in time. From a designer point of view, the *perdurantism* approach offers advantages over the *endurantism* allowing richer representations of real world phenomenon [3].

The implementation of a *perdurantism* approach within an ontology, requires the conversion of static properties into dynamic ones. The two primary Semantic Web languages are OWL and RDF, unfortunately both of them provide limited support for temporal dynamics [4]. The OWL-Time ontology describes the temporal content of web pages and temporal properties of web services. Moreover, this ontology provides good support for expressing topological relationships between times or time intervals, as well as times or dates [5]. However OWL allows only binary relations between individuals. In order to overcome this limitation several methodologies for the representation of dynamic objects and their properties have already been proposed. Among the most well known are the temporal description logic, temporal RDF, versioning, reification, N-ary relationships and the 4D-fluent approach.

Temporal RDF [6] proposes an extension of the standard RDF for naming properties with the corresponding time interval. This allows an explicit management of time in RDF. However Temporal RDF uses only on RDF triples, therefore it does not have all the expressiveness of OWL. Additionally

by using only RDF it is not possible to employ qualitative relations.

Reification [7] is a technique used to represent n-ary relations, extending languages such as OWL that allow only binary relations. In [4], the authors developed a lightweight model using Reification. The model is designed to be deployed on top of existing OWL ontologies extending their temporal capabilities. The model also implements a set of SWRL operators to query the ontology. Reification allows the use of a triple as object or subject of a property. But this method has also its limitations, for instance the transformation from a static property into a dynamic one increases substantially the complexity of the ontology, reducing the querying and inference capabilities. Additionally reification is prone to redundant objects which reduces its effectiveness.

Versioning is described as the ability to handle changes in ontologies by creating and managing multiple variants of them [8]. However, the major drawback of Versioning, is the redundancy generated by the slightest change of an attribute. In addition, any information requests must be performed on multiple versions of the ontology affecting its performance.

The 4D-fluent approach is based on the *perdurantism* philosophical approach. It considers that the existence of an entity can be expressed with multiple representations, each corresponding to a defined time interval. In the literature 4D-fluent is the most well known method to handle dynamic properties in an ontology. It has a simple structure allowing to easily transform a static ontology into a dynamic one although it has some limitations [9]. The 4D fluent approach allows the recording of frequent time slices that compose the temporal part of the entities, but can not handle explicit semantics. This fact causes two problems: 1) it is difficult to maintain a close relationship between geometry and semantics; and 2) it increases the complexity for querying the temporal dynamics and understanding the modelled knowledge. Furthermore, this approach does not define qualitative relations to describe the type of change that has occurred or to describe the temporal relationships between objects. We cannot then know which entities have undergone a change and what entities might be the result of that change. Regardless of its limitations the 4D-fluent approach offers a solid starting point for the representation temporal information in OWL. Other works such as SOWL are based on it. SOWL extends the ontology OWL-time, making it able to handle qualitative relations between intervals, such as “before” or “after” even with intervals with vague ending points [10].

B. Querying the ontology

Traditionally SPARQL has been the most common language to query an ontology. SPARQL is a W3C recommendation that operates at the level of RDF graphs. However, the queries become relatively complex in a space-temporal system. An extension of this language, st-SPARQL [11],

defines new functions that allow it to handle geometries but not temporal data. St-SPARQL is based on an extension of RDF called st-RDF that integrates contact geometries and incorporate time in RDF. St-SPARQL and SPARQL are both based on RDF graphs, therefore it is impossible to draw any inference with these languages.

In [12] the authors introduce a model in which spatial-temporal information contained in a database and a spatial-temporal inference system work together. However, no information is given on the Semantic Web technologies, only the Java language is quoted as a component of the inference engine, therefore the universality and effectiveness of the inference system can be questioned. Another work is [13] in which the authors propose a reasoning system that combines the topological calculus capabilities of a GIS and the inference capabilities of the semantic web field. However the notion of time is not incorporated into this model.

The capability of switching from quantitative to qualitative data is only possible with a reasoning system. In the case of SOWL this is possible thanks to the implementation of Semantic Web Rule Language (SWRL) built-ins. In SOWL the built-ins allow the system to infer topological, directional and metric relations between entities. Qualitative information can be inferred from quantitative one and can be used as an alternative in the case of missing quantitative data. In order to query the ontology the developers of SOWL have implemented a language similar in syntax to SQL. This language performs simple spatial-temporal querying for both static and dynamic data [10].

Our literature review suggest us that the most suitable approach to develop a spatial-temporal knowledge system should follow a 4D-fluent approach using SWRL built-ins to perform complex queries and reasoning mechanisms. In the next section we will describe how we implemented this approach in the continuum model.

III. THE CONTINUUM MODEL

The 4D-fluent approach does not allow an entity to change its nature, only allows the change of the value of some of its properties. However the semantics associated with a geometry may change. For example a land parcel may change from being forest into being urban. In this example the geometry has not changed, however there is a semantic change (See figure 1A). It is equally possible that the semantics might not change while the geometry evolves. For instance, a given urban land parcel might expand by purchasing neighbouring parcels (see figure 1B).

In order to represent a dynamic entity in the continuum model we create a set of object time slices, each constituted by three components as depicted in figure 2A:

- Semantic: To describe the knowledge associated with the entity.
- Spatial: It is the graphical representation.

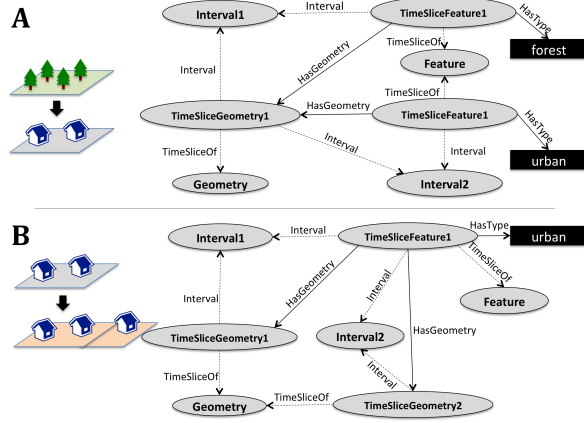

Figure 1. Examples of the evolution A) Two different semantic objects for the same geometry. B) Two related geometries for the same semantic object.

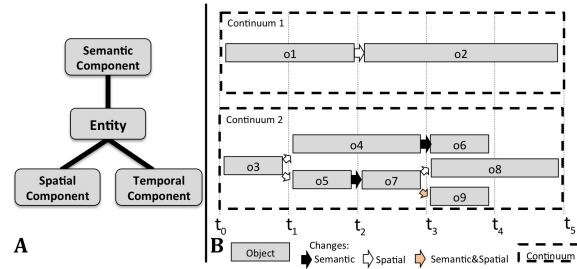

Figure 2. A) The three components of an entity within the continuum model. B) Using the continuum model to represent the evolution of an entity

- Temporal: It represents the interval or time instants that describe the temporal existence.

The goal of the continuum model is to follow the evolution of entities through time. To achieve this goal the model records the changes that entities might go through in their semantic or spatial components along time. For this purpose the model creates a new component representation every time a change occurs (spatial or semantic). The resulting child object retains all the remaining characteristics from the original parent object. Each change adds to the genealogy of the spatio-temporal objects. The parent-child relation is recorded in the system, allowing the analysis and querying of the information. The model enforces a coherency between the time intervals of objects contained in the system.

Figure 2B depicts an example of objects genealogy. In this example objects “o4” and “o5” are children of object “o3”, and are the result of an spatial change in the parent object. The system enforces temporal coherency, children objects can not occur before the parent interval. It is possible to characterize the evolution of each object in the model according to the conceptual hierarchy depicted in figure 3.

The continuum groups related objects, which have a valid

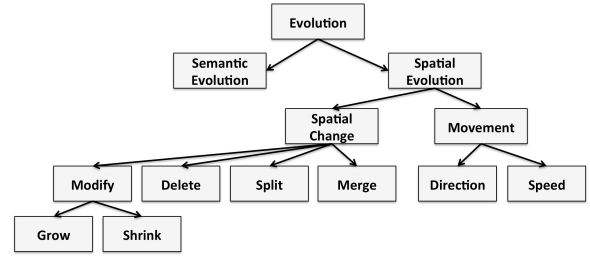

Figure 3. Qualification of transition in the spatial graph.

Figure 4. Allen temporal relations

time interval of existence. The model links individual objects to their context. For instance an object can belong to more than one continuum, therefore continuums can intersect. Our system allows the definition of qualitative relations between spatial-temporal objects, even when this object belongs to different continuums. Figure 2B depicts the evolution of an entity and how the continuum concept is used to study it.

In our model we have implemented qualitative temporal relations based on binary and mutually exclusive relations as proposed by Allen [15] (see figure 4). The addition of Allen relations increases the expressive power of the system by adding qualitative information in addition to the quantitative one. By using defined Allen relations between intervals we can obtain qualitative information even from intervals with vague endpoints in a similar fashion to [9]. For example, figure 5 depicts intervals “I1”, “I2” and “I3”. While we know the start and ending points of “I1”, we do not know the ending point of “I2”, and we do not know the starting point of “I3”. However we know that “I1” meets “I2” and that “I2” contains “I3”. Then we can infer that because “I2” contains “I3”, then “I3” must be after “I1”, even if the information about start and ending points is incomplete. Lack of knowledge caused by semi closed intervals is largely filled by the integration of Allen relations to the model.

In GIS, objects or regions are represented by points, lines, polygons or other more complex figures based on

Figure 5. Using Allen temporal relations to infer new knowledge

Table I
TOPOLOGICAL PREDICATES AND THEIR CORRESPONDING MEANINGS

Topological	Predicate Meaning
Equals	The Geometries are topologically equal.
Disjoint	The Geometries have no point in common.
Intersects	The Geometries have at least one point in common (the inverse of Disjoint).
Touches	The Geometries have at least one boundary point in common, but no interior points.
Crosses	The Geometries share some but not all interior points, and the dimension of the intersection is less than that of at least one of the Geometries.
Overlaps	The Geometries share some but not all points in common, and the intersection has the same dimension as the Geometries themselves.
Within	Geometry A lies in the interior of Geometry B
Contains	Geometry B lies in the interior of Geometry A (the inverse of Within)

these geometries. All these geometries are defined using the coordinates of points which are quantitative information. There are mainly three types of relationships between geometries: directional, metric, and topological relationships. The topological analysis between two objects is done using the models: Dimensionally Extended Nine-Intersection Model (DE-9IM) or RCC8 [16]. In both cases, we obtain an equivalent set of topological relationships for specific regions. To calculate the spatial relationships between two geometries the DE-9IM model takes into account the inside, the outside, and the contour of the geometries leading to the analysis of nine intersections as described in [16].

There are eight possible spatial relationships of the result analysis-9IM (see table I).

The relationships based on quantitative information can be translated later into qualitative data [14], in a similar fashion as we have described for the temporal aspect. By analysing a set of moments and time intervals it is possible to deduce qualitative topological relationships between objects.

In this section we use a Tarski-style specification to describe the model main components.

To represent time intervals we follow the semantics suggested by Artale and Franconi (1998). We can think of the temporal domain as a linear structure \mathcal{T} composed by a set of temporal points \mathcal{P} . The components of \mathcal{P} follow a strict order $<$, which forces all points between two temporal points t_1 and t_2 to be ordered. By selecting a pair $[t_1, t_2]$ we can limit a closed interval of ordered points. The set of interval structures in \mathcal{T} is represented by \mathcal{T}_{\leq}^* [17].

Temporal Points:

$$\mathcal{P} \quad \mathcal{P}^I \subseteq \Delta^I$$

Time Intervals:

$$\mathcal{T}_{\leq}^* \quad [to, tf] \doteq \{x \in \mathcal{P} | to \leq x \leq tf, to \neq tf\} \text{ in } \mathcal{T}$$

To define the relations identified by Allen[15] (See figure 4) we first define two intervals $i1$ and $i2$: $\mathcal{T}_{\leq}^*(i1)$, $\mathcal{T}_{\leq}^*(i2)$, being i_{to} the starting point and i_{tf} the ending point of the intervals.

Before

$$Before(i1, i2) \quad (i1_{tf} < i2_{to})$$

Meets

$$Meets(i1, i2) \quad (i1_{tf} = i2_{to})$$

Overlaps

$$Overlaps(i1, i2) \quad (i1_{tf} > i2_{to}) \wedge (i1_{tf} < i2_{tf})$$

Starts

$$Starts(i1, i2) \quad (i1_{to} = i2_{to}) \wedge (i1_{tf} < i2_{tf})$$

During

$$During(i1, i2) \quad (i1_{to} > i2_{to}) \wedge (i1_{tf} < i2_{tf})$$

Finishes

$$Finishes(i1, i2) \quad (i1_{to} > i2_{to}) \wedge (i1_{tf} = i2_{tf})$$

Equals

$$Equasl(i1, i2) \quad (i1_{to} = i2_{to}) \wedge (i1_{tf} = i2_{tf})$$

The Spatial representation of an object (\mathcal{SR}) is composed by a spatial reference system (SRS) and a geometry (\mathcal{G}) (A more complex definition is possible, however for the sake of simplicity we will refer only to the essential components of a geographic feature definition).

Spatial Reference System: As defined by the European Petroleum Standards Group (EPSG) [18]

$$SRS \quad SRS^I \subseteq \Delta^I$$

Geometries: A set of coordinates that define points, lines, curves, surfaces and polygons.

$$\mathcal{G} \quad \mathcal{G}^I \subseteq \Delta^I$$

$$\forall HasSRS.SRS \equiv \{x \in \Delta^I | \forall s.(x, s) \in HasSRS^I \rightarrow s \in SRS^I\}$$

$$\forall HasGeom.\mathcal{G} \equiv \{x \in \Delta^I | \forall g.(x, g) \in HasGeo^I \rightarrow g \in \mathcal{G}^I\}$$

Then the spatial representation can be defined as:

$$\mathcal{SR} \equiv \forall HasSRS.SRS \sqcap \forall HasGeom.\mathcal{G}$$

The spatial relations between geometries are defined by the Extended Nine-Intersection model (DE-9IM) [16].

The semantic component of the objects is represented by \mathcal{S} . It describes the nature of the entities and can be composed by one or more alphanumeric properties.

Each object time slice (\mathcal{O}) in the continuum model has three components: 1) a time interval (\mathcal{T}_{\leq}^*), 2) a spatial representation (\mathcal{SR}) and 3) a semantic component (\mathcal{S}).

$$\mathcal{O} \equiv \forall HasSR.SR \sqcap \forall HasInterval.\mathcal{T}_{\leq}^* \sqcap \forall HasSemDef.\mathcal{S}$$

In the continuum model a change on the spatial representation or on the semantic component generates a new object which has a *child - parent* relationship with the original object, additionally we know that the time interval of the parent object *meets* the time interval of the child object (see figure 4). The parent child relationship between object $o1$ and $o2$ is defined by the relationships between their spatial representations ($o1_{sr}$ and $o2_{sr}$), their semantic definitions ($o1_s$ and $o2_s$) and their time intervals ($o1_i$ and $o2_i$)

$$\forall HasChild.\mathcal{O} \quad \{o1 \in \mathcal{O}^I | \forall o2.(o1, o2) \in HasChild^I \rightarrow o2 \in \mathcal{O}^I \wedge \exists((o1_{sr} \neq o2_{sr}) \vee (o1_s \neq o2_s)) \wedge (meets(o1_i, o2_i))\}$$

where: $\{o1, o2\} \in \mathcal{O}$, $\{o1_{sr}, o2_{sr}\} \in \mathcal{SR}$ and $\{o1_s, o2_s\} \in \mathcal{S}$

The spatial transitions in the model are a subset of the *HasChild* relationship: *SpatialEvolution* \sqsubseteq *HasChild*. We have implemented the following spatial transitions: (see table I for a definition of topological relations)

Merge	$Merge(input, output)$ $input = \{a_1, a_2 \dots a_n\} \forall x \in input \rightarrow SR(x)$ $SR(output)$ $Equals((a_1 \cup a_2 \cup \dots a_n), output)$
Split	$Split(input, output)$ and $SR(input)$ $output = \{a_1, a_2 \dots a_n\} \forall x \in output \rightarrow SR(x)$
Equals	$Equals(input, (a_1 \cup a_2 \cup \dots a_n)) \wedge$ $\forall (a, b) \in output \times output a \neq b \rightarrow$ $\neg overlaps(a, b)$
Delete	$Delete(input, output)$ and $SR(input)$ $Equals(output, \emptyset)$
Grow	$Grow(input, output)$ and $(input, output) \in SR$ $Within(input, output)$
Shrink	$Shrink(input, output)$ and $(input, output) \in SR$ $Contains(input, output)$

IV. EXAMPLE CONTINUUM

The continuum model is flexible enough to be adapted in multiple fields. For this example we will use it to study the urban evolution of the city of New Orleans, Louisiana. Figures 6 and 7 represent the urban evolution of the entity “city of New Orleans”. Each one of its multiple representations along its history is a *time slice*.¹ Figure 6 depicts the urban evolution of the city, we can see the historic French Quarter, founded in 1718 (Figure 6A), and how the city grew until around 1853 (Figure 6C) when it went through a conurbation process with the cities of Greenville, Jefferson and Lafayette (Figure 6B). The city continued its growth and by 1949 it reached its approximately modern size. In August of 2005 Hurricane Katrina landed near the city causing a major flood, also depicted in figure 6D. First we define the class Human Settlement (\mathcal{HS}) as a subclass of the objects (\mathcal{O}),

$$\mathcal{HS} \sqsubseteq \mathcal{O}$$

therefore it has all three components, spatial (\mathcal{SR}), temporal (\mathcal{T}) and semantic (\mathcal{S}).

The conurbation process involves two cities merging. Using the model we can represent the process as:

$$\{a1, b\} \in \mathcal{HS} | Contains(a1_{sr}, b_{sr}) \wedge Meets(a1_i, b_i) \\ \rightarrow ConUrbation(a1, b)$$

Figure 9 depicts the form how the model will be used in the New Orleans example. The spatial representation of the time slice *Nola2* contains the spatial representation of

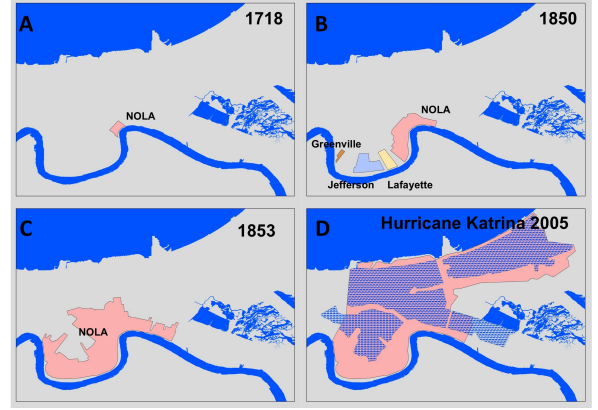

Figure 6. City of New Orleans along time

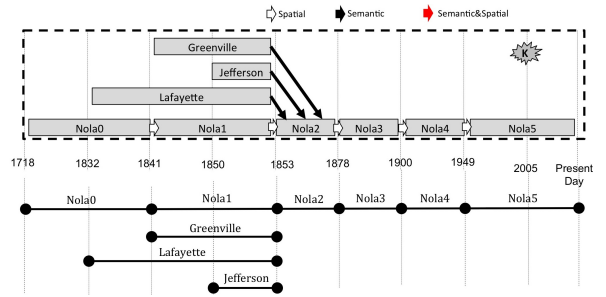

Figure 7. Time frame of urban evolution

Jefferson, therefore there is a conurbation process by the year 1853.

Figure 6D depicts the area flooded by Hurricane Katrina in 2005. We can create a new class *risk areas* as \mathcal{RA} ($\mathcal{RA} \sqsubseteq \mathcal{O}$), representing the flooded area. Then we can identify the process *growth in risk area* as:

$$\{a, b\} \in \mathcal{HS} \wedge r \in \mathcal{RA} | Grow(a, b) \wedge \\ (Overlaps(a_{sr}, r_{sr}) = \emptyset) \wedge \\ (Overlaps(b_{sr}, r_{sr}) \neq \emptyset) \\ \rightarrow GrowthInRiskArea(a, b)$$

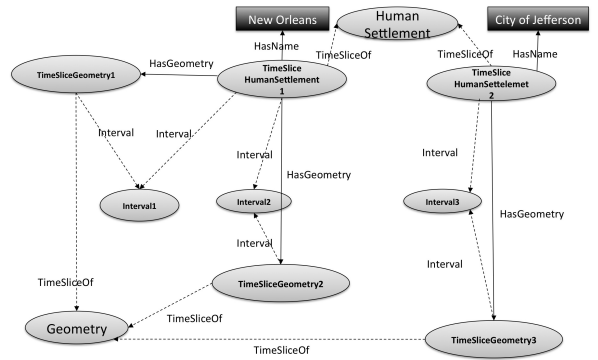

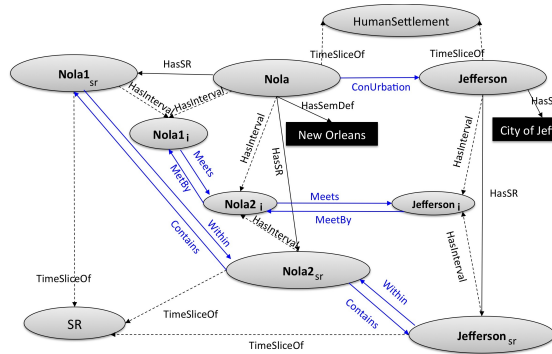

Figure 8. Representation using the 4D fluent

¹The depiction of the urban evolution was created by us, based on scanned historic maps, however it should not be taken as totally historically accurate because it was simplified for this example.
